

# Expectation and Variance

## Definition: Expectation

The expectation of a *real* random variable  $X$  is defined as

$$\mathbb{E}[X] := \sum_{x \in \mathcal{X}} P_X(x) \cdot x.$$

Note that if  $X$  is not real, then we can still consider the expectation of some function  $f : \mathcal{X} \rightarrow \mathbb{R}$ , where

$$\mathbb{E}[f(X)] = \sum_{x \in \mathcal{X}} P_X(x) \cdot f(x).$$

## Definition: Variance

The variance of a *real* random variable  $X$  is defined as

$$\text{Var}[X] := \mathbb{E}[(X - \mathbb{E}[X])^2].$$

The variation is a measure for the deviation of the mean. Hoeffding's inequality (here stated for binary random variables) states that for a list of i.i.d. random variables, the average of the random variables is close to the expectation, except with very small probability. We state it here without proof.

## Theorem: Hoeffding's inequality

Let  $X_1, \dots, X_n$  be independent and identically distributed binary random variables with  $P_{X_i}(0) = 1 - \mu$  and  $P_{X_i}(1) = \mu$ , and thus  $\mathbb{E}[X_i] = \mu$ . Then, for any  $\delta > 0$

$$P \left[ \sum_i X_i > (\mu + \delta) \cdot n \right] \leq \exp(-2\delta^2 n).$$
