Definition: Binary Entropy

For a binary random variable X with image $\mathcal{X}=\{x_0,x_1\}$ and probabilities $P_X(x_0)=p$ and $P_X(x_1)=1-p$, we can write H(X)=h(p), where h denotes the binary entropy function:

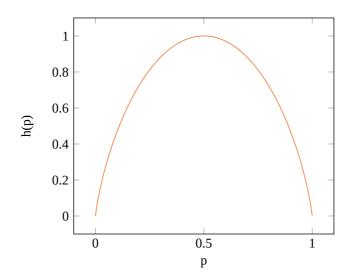

Definition: Binary entropy function h

The binary entropy function is defined for 0 as

$$h(p):=p\log\frac{1}{p}+(1-p)\log\frac{1}{1-p},$$

and is defined as h(p) = 0 for p = 0 or p = 1.

The graph of h on the interval [0,1], as a function of p, looks as follows:

If we think of X as the random variable describing the outcome of a coin flip, we see that a relatively fair coin $(p \approx \frac{1}{2})$ yields a higher expected surprisal value than a very biased coin (where p is closer to 0 or 1). If the coin is completely fair ($p=\frac{1}{2}$), the entropy is exactly 1 bit.
